response to request for a copy of draft Hangar 6 health consultation Thursday, December 02, 2010 8:49:41 AM

Date: Attachments:

FOIA request Constantino Nov2010.pdf Et Wainwright AK Hangar 6 Nov 26 2010 mw DRAFT.docx

Dear Mr. Constantino:

In response to your public records request dated November 22, 2010 (see attached), and pursuant to the Alaska Public Records Act (AS 40.25.110-125), please find attached a DRAFT version of the health consultation report titled Chemical Exposure Incident at the Hangar 6 Construction Site, June 29th and 30th, 2006, Fort Wainwright, Alaska.

Please recognize that as a draft document, the contents of this report could change significantly in the final version. This draft was prepared by the Alaska Department of Health and Social Services under a cooperative agreement with the Agency for Toxic Substances and Disease Registry (ATSDR). As such, all health consultations must be submitted to ATSDR for their review process before it becomes a final public document. We submitted this draft to ATSDR last Friday, November 26, 2010.

Thank you for your request. Please let me know if I can be of further assistance.

Regards,

Chung Nim Ha, MPH Acting Program Manager Environmental Public Health Program Section of Epidemiology Alaska Division of Public Health 3601 C Street, Suite 540 Anchorage, AK 99503 (907) 269-8028 nim.ha@alaska.gov

Health Consultation

Chemical Exposure Incident at the Hangar 6 Construction Site, June 29th and 19th 2006

FORT WAINWRIGHT, A ASKA

Alaska Department of Health and Social Services Division of Jublic Health, Epidemiology Section Environmental Public Health Program

Under Cooperative Agreement with the Agency for Toxic Substances and Disease Registry

SUMMARY

INTRODUCTION

At Fort Wainwright, ATSDR's top priority is to ensure that base residents, workers, and visitors have sufficient information to safeguard their health. Several workers were exposed to a chemical that was released during site construction activities on June 29th and 30th, 2006, and the workers subsequently complained of health effects following the incident. The purpose of this consultation was to evaluate environmental chemistry data and the medical records of several exposed workers to determine what the workers may have been exposed to, whether the exposure event harmed their health, and whether the site poses a current or future risk to the public

OVERVIEW

ATSDR reached two important conclusions about the Hangar 6 site at Fort Wainwright Alaska

CONCLUSION 1

ATSDR concindes that digging the soils in the exclusion zone of the Hangar value posed a past produc health hazard to workers due to the risk of breathing or unknown chemical released from the soil. But hing the unknown chemical for a short period of time (less than the day) harmed people's short term right.

BASIS FOR DECISION

Mississ to worke interviews and other site documents suppose the conclusion that multiple workers were exposed to an aknow themical on June 29th and 30th, 2006 that harmed their site t-term. The chemical was released into the air when it was exposes during construction excavation activities.

NEXT STEPS

The area where the chemical exposure occurred during excavation activities has been permanently covered by a parking lot. This means that if any of the unknown chemical is still present in a pocket of the soil it would no longer be a public health hazard because it cannot reach people's breathing zone.

CONCLUSION 2

ATSDR concludes that breathing air at the Hangar 6 site at the present time will not harm people's health. It will continue to pose no risk to public health in the future, as long as the exclusion zone remains capped and undisturbed.

BASIS FOR DECISION

The area where the chemical exposure occurred during excavation activities has been permanently covered by a parking lot. This means that if any of the unknown chemical is still present in a pocket of the soil it would no longer be a public health hazard because it cannot reach people's breathing zone.

During environmental sampling activities that were initiated following the exposure incident in June 2006, no chemicals were found in soil, soil vapor or air at levels or health concern.

NEXT STEPS

ATSDR recommends that the permanent pailing lot "cap" on the Hangar 6 exclusion zone site should not be distribled at any time in the future without constiting environmental regulators. If excavation is ever plantation to the site in the future, an otective health and safety plan should be described and implemented that takes the potential respiratory numerics to workers into account.

FOR MORE INFORMATION

If me have question about this port, you should contact Alaska. Environmental Public Health Program (EPHP) at (907) 269-800. You can also call ATSDR at 1-800-CDC-INFO and for it formation about the Hangar 6 site at Fort Wainwright,

Statement of Issues

This health consultation focuses on an incident that occurred June 29th and 30th, 2006 on a construction site at Fort Wainwright, Alaska. While excavating at the construction site known as Hangar 6, multiple workers reported being exposed to a chemical that sickened them. While some of the people reporting exposure have recovered, several workers complain of on-going chronic health effects as a result of the exposure.

At the request of multiple entities, including the injured workers, the Alaska Department of Environmental Conservation (ADEC), and the U.S. Army, the Alaska Division of Public Health (ADPH) and Agency for Toxic Substances and Dicease Registry (ATSDR) have collaborated to conduct an independent investigation of the exposure incident. The purpose of this health consultation is to examine available invita mental sampling data and employee medical records in an attempt to determine what the lorkers may have been exposed to, and whether their acute, short-termine volume-term ealth symptoms may be related to chemical exposure at the site. The current and future least of the site is also discussed.

Authority

On October 24, 2006, ADPH requested comission from ALDR to perform an independent assessment of environmental as health data from the Hangar 6 incident On November 20, 2006, Thomas Sinks from ATSDR adjusted that ATSDR would formally request funding from the Department of Defense (DOLL) a conduct an evaluation of the Hangar 6 incident through the cooperative as feement program. This was necessary, because the cooperative agreement program is supported by CERCLA funds and a DOD facility health consumation was a tiside of this authority. At ATSDR's request, ADPH submitted a proposed scan of sock timeline and budget for the project to ATSDR on January 5, 2007. DOD substituting apply to the activity and provided funds to ATSDR for a health consumation; these ands were passed through to ADPH to conduct the assessment.

Background

Fort Wainwright, an active military installation covering approximately 915,000 acres in the Fairbanks New Star Borough, Alaska. Fort Wainwright, originally referred to as Ladd Army Airfield and Ladd Air Force Base, has been in continuous service by the military since 1938. During World War II, the installation served as a crew-transfer point in the Army Air Corps' Lend Lease program. In 1947, the newly established U.S. Air Force used the facility as a re-supply and maintenance base for the remote Distant Early Warning Sites and as an experimental station in the Arctic Ocean. In January 1961, all base operations were transferred back to the U.S. Army and the base was renamed Fort Wainwright. The primary current mission of the installation is to train U.S. Army infantry soldiers in the arctic environment, and to prepare troops for rapid deployment worldwide.

Over decades of military use, routine operations, storage practices and former waste disposal practices resulted in accidental releases of chemicals to the environment at Fort Wainwright. In August 1990, Fort Wainwright was placed on the National Priorities List because of contaminated areas on the installation. The most common contaminants at the base are volatile organic compounds, pesticides, polychlorinated biphenyls (PCBs), petroleum, oils, and lubricants. Fort Wainwright also received small quantities of radioactive tritium waste and low-level radioactive materials. A Chemical Warfare Disposal Area was located at the base of Birch Hill on base; 20 to 30 cylinders of mustard agent were buried in a trench there in 1946 or 1947. In 1966, seven cylinders and an unknown number of crates were removed from the area; subsequent activities in the 1990s documented the absence of chemical warfare materials and their breakdown products at the site (ATSDR 2003).

ATSDR has conducted a number of public health activities at Fort Mainwright over the past two decades. As part of the public health assessment process, ALDR conducted site visits to the installation in 1991, 1998 and 2007. During the 1998 was ATSDR met with some of the residents of on-base and nearly off-base communities, an identified two public health concerns that were further evaluated. On individual was oncerned about possible exposure to harmful levels of contaminates in lawn-irrigation water drawn from the Shannon Park Baptist Church private well, who was known to be contaminated with Volatile Organic Charicals (VOCs). A SDR prepared a health consultation to address the concern, and consided that no public health hazard existed from contact with this irrigation water (A SDR 199a). Another community member was concerned about learning disabilities and at entions distributed disorders among children attending two schools satisficance to address this concern, which documented that children who attended the two school did not suffer from a higher incidence of learning disabilities than children statewide (TSD 199b). A conprehensive Public Health Assessment evaluating contaminant issue across and the installation was published in September 2003 (AT DR 2008).

Hangais or former Built of 2085 was destroyed by a fire in August of 2004. Historical records into the that solvery associated with washing of aircraft and helicopter parts were used at the facility, in addition to typical fuels and lubricants associated with military operation. (North Wind 2007). Hangar 6 was a designated Hazardous Waste Accumulation point of the maintenance of Chinook helicopters, using a Petroleum, Oil, and Lubricants (POL) shed with slated mesh fence walls and a drip pan floor (ADEC 1990). The chemical exposure incident on June 29th and 30th, 2006 occurred among workers preparing the Hangar 6 area for construction of a new hangar and parking lot in the same location.

About a week after the chemical exposure incident, Dr. Larry Harikian of the Urgent Care Center in Fairbanks became the primary care provider for the four workers who had reported to Fairbanks Memorial Hospital on June 30th, 2006. He began evaluating those four workers, as well as another employee not originally seen but deemed to be more highly exposed and symptomatic, and around 30 or more others who were sent by the

employer for evaluation though either asymptomatic or mildly symptomatic. Dr. Harikian was the designated primary care provider by the Alaska National Insurance Company (ANIC), the workers compensation vehicle for Alaska.

Numerous diagnostic tests were run without revealing any common findings, and symptoms/health effects in the workers were persisting and evolving. Dr. Harikian called a consultation line to the University of Washington Medical Center in Seattle for medical toxicology expertise and began working with Dr. Thomas Martin, an Occupational Medicine physician and Medical Toxicologist. One course of action was to send the five workers with the most severe symptoms to consultants: two went to the University of Washington (Dr. Matthew Keifer, and Dr Jordan Firestone), two went to the Oregon Health and Sciences University in Portland (Dr. Melanie Saur in and one went to the Mayo Clinic in Minnesota.

Dr. Martin also recommended that a medical panel be cordinated and convened to review the environmental sampling and clinical evaluations pertaining to the exposure incident. A panel was assembled which include the physicians involved to are named above, a medical epidemiologist and an environmental toxid logist from the Alaska Division of Public Health, a medical doctor from the CArmy Center for Health Promotion and Preventive Medicine (USACHPPM), a cartified industrial hygienist from the construction contractor involved, and two representative from the US Army Corps of Engineers (USACE). ADPH is only aware to see meeting of the panel, on September 1st, 2006; they participated in that conference call. It was meetings of the panel were to be called by ADPH following their review of the avironmental data. Unfortunately, ADPH's environmental at the of the data of not occur in a timely enough manner to accomplish the stated toals of the medical panel, due to lack of sufficient resources.

Methods

Two recorts that had pure lously to prepared regarding this incident were reviewed as part of it shealth consultation. US CHPPM prepared an occupational and environme of health risk a ressment of the Hangar 6 exclusion site in April 2007 (USACHPPM 207). The purpose of that document was to evaluate existing environmental sampling data to determine whether the site was safe for construction workers to resume that excavation, grading and paving work at the site. It was not within the scope of the USACHPPM report to evaluate the exposure incidents of June 29th and 30th, 2006 themselves, or to evaluate the health concerns of the exposed workers from that incident. The second report evaluated was a Site Investigation and Removal Action Technical Memorandum dated September 2007, which describes environmental sampling events that occurred during the period July 2006 through September 2006 (North Wind 2007). Extensive appendices of environmental sampling data from that report formed the basis for the ADPH and ATSDR environmental data review.

In addition to these reports, information was gathered from a number of additional sources. These included:

- Participation by ADPH (Lori Verbrugge) in various site update meetings with the USACE, ADEC, the U.S. Army Dept. of Public Works, Bristol Company, USACHPPM and others, August 2006 through June 2007
- Medical Panel conference call September 1st, 2006 attended by ADPH (Verbrugge);
- Site visit by ADPH (Verbrugge) on November 7th, 2006;
- Consultation, collaboration and brainstorming with medical doctors from USACHPPM (Vivian Rush) and ATSDR (Juliana Grant and Michelle Watters);
- Interviews of five injured workers by ADPH (Verbrugge), July 2007 through April 2008;
- Individual medical records from five injured workers, died from the period June 29th, 2006 through March 31st, 2008.

Health Records Review

Health records including clinical records, worker injury reports and the UACHPPM Health Risk Assessment (USACHPPM 2007) reviewed in an effort to practerize the possible chemical exposure based in part on the lens and symptoms attributable to specific chemical exposures. After receiving individual vorker's consent for the release of confidential medical information, the ADPH obtained redical records for five of the workers involved in the incident. For the least part, the record covered the time period between June 29, 2006 and March 31, 2008. In medical records prior to the incident were provided. Worker telephone interviews we conducted by the ADPH in 2007 and 2008.

For the five health reards reviewed, signs and symptoms were categorized for four time periods: immediate on a scute inset (occurring within 2 weeks of exposure), short-term duration (occurring or periotting to 3 months), and long-term duration (persisting for greater than boths, periods) until warch 31st, 2008). In an effort to ensure the privacy of the individuals involved this information is presented collectively or is deidential to the extent pariods.

Non-Clinica Medical Reports Review

Non-clinical documents related to symptoms and other health issues were reviewed, including findings in the Medical Panel convened for the incident and a spreadsheet of symptoms from 19 workers.

Environmental Data Review

Analytical laboratory reports for the post-incident site investigations, as listed in Appendix A, were obtained and reviewed. Quality assurance summaries were reviewed for the reports, and the data were compiled into summary tables (Appendices B-E). Detected chemicals were compared to health-based screening values established by ATSDR, the U.S. Environmental Protection Agency (EPA), or the National Institute for

Occupational Safety and Health (NIOSH) when available. The health-based screening criteria are described in Appendix F.

Comprehensive data validation, such as review of raw data and chromatograms with verification of calculations, was not within the scope of the ADPH and ATSDR review of this large data set. Reported chemical concentrations in final analytical reports were taken at face value and assumed to be accurate.

Comparison of chemical concentrations in soil and soil gas (the atmosphere present in soil pore spaces) with health-based screening criteria, as documented in Appendices C and D, was limited by the following factors:

- 1) Screening values were not available for many of the dected chemicals;
- 2) Soil samples were not collected at the time the harmful posure occurred; they were collected weeks to months later. Twenty-six of the 3d foil samples collected on September 22-27, 2006 were taken from the top six inches of the soil after clean fill material was added and the site was re-graded, in order confirm that the area was clean and that it was safe to some construction.

Screening values for contaminants in soil are usually and on a soil ingestion pathway. Screening values to evaluate an inhalation pathway from a il are only available for volatile organic chemicals (VOCs), from the USEPA. Since the relevant exposure pathway for the Hangar 6 incident was talk alon, it is most back that a volatile chemical was the causative agent. While ATSDR soil screening values are listed in Appendix C for all available chemicals for the sake of completenes. To see shown for all chemical classes except VOCs are all in ited meaning ince they are based on the ingestion pathway.

The soil gas evaluations in Approxime D represent an over-estimation of inhalation risk because they assume the soil gas was an inhaled. In actuality the soil gas would likely be fluited by a bient are gior to reaching the breathing zone of workers.

It was not within the scope of work for this document to duplicate the risk assessment work perfected by USAC PM, as their report evaluated the same set of environmental data. Instead, he risk assessment methodology of USACHPPM was evaluated for appropriateness assumptions (Appendix G), and several representative calculations were checked for accuracy. The USACHPPM risk assessment was then deemed to be well-done and valid, and the results were carried forward for further consideration from a public health perspective. Conclusions from the USACHPPM risk assessment are provided in Appendix G as a convenience to the reader who may not have access to this document.

Results and Discussion

Summary of Worker Interviews

The following summary of the events of June 29th and 30th, 2006, is gleaned from interviews with the ill workers, information provided by installation staff, company staff and regulators, and USACHPPM's report and correspondence. There is no record of personal protective equipment worn, but interviews do not indicate that respiratory or eye protection was used during the excavation.

An excavation was occurring in an open area at the Hangar 6 constitution site on June 29th, 2006, in preparation for construction of a parking lot. For owing sub-grading activities at least two workers observed a clay layer, approximately 4 inches deep, covering a portion of the site at the southwest side of the langar, do ribed by one as "an almost perfect thirty-foot circle". When a caterpillar perator dug through the clay layer he noticed a "funny odor". He began to experience headaches and nause and after about an hour he left his caterpillar and notified its supervisor. They contained the safety officer and the worker reported to Fairbanks Membraial Hospital. He was placed in a decontamination shower and given medicine for nause the went home, and reported to work the next day. Other workers mentioned during into views that they smelled the odors on June 29th, but they did not see the dical care that they one of the workers spent time near the dirt pile from the contaminated and doing concilinate area. A dirt pile pushed up from the contaminated and after a fenced off thing yellow caution tape.

Work continued on Jul 30th outside the immediate area, but downwind of it. The original worker and three others bean noting samptoms again, along with the bad, strong odor. One werker was in a sitch and were come when he climbed out of the ditch. Another worker was than enclosed cab of a backhoe and was overwhelmed when he exited be cab. At least our workers reported falling to their hands and knees and vomiting the voluntarily are a site the day. In addition to a dry or chalky sensation in the upper airwal (mouth and the oat), common symptoms included nausea and vomiting and abdominal characteristic, lighth adedness or dizziness and bad headache, muscle and joint achiness and were less, so the complaint of chest tightness or cough, and some complaint of numbness in the strengties. The ill workers reported to Fairbanks Memorial Hospital, where they were decontaminated in the ambulance bay. Several of the workers stated that they waited a long time to be evaluated at the hospital, and were eventually spoken to by a doctor from the military (not from Fairbanks Memorial) and then released. Most of the workers continued to seek medical care for weeks to months following the incident, due to continuation of symptoms.

The odor detected by the workers was difficult for them to describe, even though they were experienced construction workers quite familiar with commonly-encountered odors such as petroleum, benzene and solvents. The following comments were made by workers when asked to describe the odor: "obnoxious", "never smelled anything like it",

"funny", "burned nose; chalky taste on lips", "like old fuel, or rotting diesel", "pungent", and "strong".

Five of the workers continued to experience symptoms that they attribute to the exposure incident on June 29th and 30th, for months or even years following the event. Those concerns are evaluated in the "health records review" section below.

Worker interviews revealed that a field screener was not on site during the exposure incident on June 29th and 30th, 2006. The purpose of a field screener is to monitor ambient air quality for the presence of chemicals at hazardous levels while construction is in progress. The USACHPPM report indicates that a field screener was required to be physically present on the site with a Photoionization Detector (ID) if more than 6 inches of soil was being removed.

Interviews with workers and site project managers alto evealed that, overal weeks prior to the June 29th and 30th chemical exposure incident, an unexploded ords area (a live mortar shell) was uncovered while digging at the Hangar 6 site. Fortunated the area was evacuated and no one was injured. Nevertheless, the evident that a physical mazard at the site also posed a potential risk to worker safety.

Health Records Review

Incident history and symptoms

Workers consistently remained foul, nasty shelling oder at the time of the incident. Although one worker rescribes the smell as being similar to benzene, most were unable to further describe the cell other than stating that it was not a more familiar smelling volatile chemical such as a fuel conjugant. Healtache and nausea associated with dry heaves were abstracted as ponses, and workers reported stomach pains and cramping and lights bledness of dry, chalky or metallic taste, shortness of breath, eye irritation and skin irritation were prious symptoms reported by several workers. Some reported hore immediate asset of ryalgia (pain in muscles) and arthralgia (pain in joints).

In the days following the incident, headache, light-headedness and nausea persisted in most of the worker. Veniting or dry heaves, anorexia, stomach cramps and gastrointestinal upset were also prevalent symptoms. Most of the workers also reported paresthesia (abnormal skin sensations such as tingling) of the hands and feet and myalgia. Several reported fatigue or muscle weakness. For various workers loose bowels or bloody diarrhea, sore throat, laryngitis, difficulty concentrating or short term memory loss and hematuria (blood in the urine) were reported.

The most common symptoms that persisted during the first few months for the five workers were fatigue (n=4), headache, nausea, and paresthesia of the hands and feet (n=3), and light-headedness (n=2). Most workers were reporting gradual improvement in either the frequency or intensity of the symptoms. Through the end of the first 3 months,

various workers reported on-going difficulty with balance or dizziness, laryngitis, and shortness of breath.

Of the few medical records available for workers beyond 3 months post-incident, continued nausea, light-headedness, dizziness and paresthesia of the hands and feet were reported by two workers and headaches by three workers. Other long-term symptoms reported by one worker included difficulty concentrating and memory loss.

Physical exam findings

The four workers brought to the emergency room after the chemical exposure on June 30^{th} were decontaminated by showering and provided hospital gawns to wear prior to being examined. In general, there were few positive physical indings reported. Vital signs were normal (pulse rate, respiratory rate, temperature and blood pressure). All had a percent oxygen saturation 96% or greater. With the exception transfor three of the four workers a slight conjunctival injection (bloodshot exception transfor three of the four workers a slight conjunctival injection (bloodshot exception transfor three of the four workers a slight conjunctival injection (bloodshot exception) was noted, in head and neck exam was normal. No miosis (constricted pupils) was reported. There was no abnormal cardiovascular, respiratory, gastrointestinal, or many system findings now. For each worker, no abnormalities of the neurological exam were found including gross exam of cranial nerves II-XII, motor function and strength, research, gait, coordination, and sensation. There were no acute dermatological condition reported.

One of the workers had visited the emerican coom on June to for a similar work exposure. With the exception of an elevated blood ressure or that day, the physical exam was normal. Another of the four workers eturned to the emergency room on July 1st, 2006. His physical to the switchin normal limits.

Medical records for chick visits or all five of the workers were reviewed for pertinent physical exam findings with following the chemical exposure. During this period, a few physical exam indings were need that were consistent with self-limited conditions including their resultatory infections or with pre-existing chronic conditions such as appertension. There workers had various dermator gical findings noted. One worker had and neck exam. Three workers had various dermator gical findings noted. One worker had a dry scaly patch on the chest and a dry tesion on an upper eyelid, and another had an erythematous (red) patch on the chin with subsequent exams reporting hypopigmented areas on the chin and ankle suggesting are lous vesicles (very small blisters). One individual had right upper quadrant tende ness noted on two exams. Poor coordination, difficulty with balance, loss of two point discrimination (a neurological test for sensation), slight tremor, lid lag, and decreased grip strength were the abnormal neurological physical exam findings reported for three of the five workers, although there were no findings common among the workers.

There were several medical records provided for 4 of the workers for periods greater than 3 months post-exposure. Many of these were from specialists, therapists, and independent medical evaluators. Positive Tinel's and Phelan's tests (exam tests for the median nerve) were noted for an individual who was diagnosed with carpal tunnel

syndrome. A decreased response to pinprick, temperature and proprioception (position sense) was reported for another worker.

Weight was recorded for four workers, beginning 1 week or more post exposure. All four of these workers weighed over 200 pounds. One was noted as being obese. Over the period the medical records covered, one worker remained within 5% of his average weight, one worker gained twenty pounds over five months, and one gained 15 pounds in one week from his first measurement and remained the same weight in subsequent follow-ups. One worker had a precipitous drop of approximately 25 pounds between the second and third month post-exposure.

Laboratory findings

Results from general laboratory analyses including complete bland count, comprehensive metabolic panel (electrolytes, hepatic function, renal function), and trinalysis were provided for the workers during various medical visit over the first to ponths post exposure. All the results were either within or close to the normal laboratory reference range. The values that were slightly above the discrence range were consist to with use of prescribed medication or acute self-limited illing.

Several blood and urine laboratory analyses were performed for specific chemicals. However, because these chemicals have bort biological have lifes, these samples were not collected close enough to the time of the stual exposure in trent in order to be useful in understanding what chemical the worker might be been exposed to for an acute one-time exposure. Therefore, non-detects or normal value and indicate that the worker was either never exposed in the longer being exposed in that chemical.

One week post exposure laboratory results for ablood xylene exposure profile (o-xylene, m-xylene, p-xylene, 2-na hylhi duric acid, 3-+ methylhippuric acid, and total methylhippuric acids) were solvided to a gray of the workers. All results were non-detect for these deasures. I cause a the short half life of xylene in the blood, a blood xylene exposure profile must be be performed within hours of exposure.

Six weeks test exposure, can worker had plasma and RBC cholinesterase levels analyzed. Typically, the dustion of a depression of RBC cholinesterase is a few days to a few weeks. The results were within the normal reference range and no prior analyses were provided (for the rorker) for comparison.

Six to 10 weeks post exposure, two of the workers had 24 hour urine testing for four heavy metals (arsenic, lead, mercury, and cadmium). For these metals, urine samples should be taken at least within a few days of an acute exposure. All results were reported as either non-detect or below the background reference range. One worker had a 24 hour urine total arsenic specimen submitted 4 months post exposure, this result was also below background.

Imaging studies

All 5 workers had at least one chest x-ray within the first 2 months post-exposure. Two were noted to be unremarkable or normal. Three workers had follow-up computed tomography (CT) of the chest based on the chest x-ray. Two of the worker's CT results did not suggest any acute abnormalities or process. The third worker's follow-up CT suggested small airway inflammation that may be related to acute/subacute hypersensitivity pneumonitis or inhalational insult.

Other imaging performed between the second and third post exposure month on one or two of the workers included CT of the abdomen, ultrasound of the abdomen and magnetic resonance imaging of the head. All of these imaging points were reported as being within normal limits.

Other testing

One month or more post exposure, pulmonary function esting was patermed on all of the workers. With few exceptions, the results were within normal limits. A series of pulmonary function testing on one worker demonstrated a mild restrictive patern, normal results, and a mild obstructive pattern. One works a result showed a mild eversible small airway disease; his follow-up testing was normal.

A couple of workers had nerve conduction and electromyou phy of their extremities performed. One worker was identified as had a median nerve curopathy and diagnosed with carpal tunnel syndrome. The other lide not show any electophysiologic evidence of any neuropathy, radiculopathy or any opacity.

Neuropsychiatric and speech exputations were performed on two workers several months after the exposure. In tressions included: functioning was within expected and normal range across all domains itssess and action in issual processing abilities, anxiety, depression, mild-negnitive includies, the different in basic reasoning, mild to moderate cognitive inguistics to cit. One worker had an electroencephalogram reported as within normal limits.

There were ar, nose and the at referrals for several workers. One month post exposure, flexible fiberal ic laryngos by was performed for a worker. The impression was laryngitis second by to checkical exposure by history. Several months post exposure, two workers received verifical exposure by history. Several months post exposure, two workers received verifications. Impressions from these tests included a possible left peripheral vestibular lesion, bilateral vestibular deficits, sensorineural hearing loss and mixed type hearing loss. No pre-exposure audiometric evaluations were available for comparison. One worker had a physical therapy evaluation that supported the impression of the balance and vestibular (related to the sense of equilibrium) problems.

Gastrointestinal evaluation carried out three months post exposure on two workers included a gastric emptying study that revealed rapid gastric emptying, a small bowel biopsy that was normal, a stomach biopsy that suggested reactive gastropathy, and a colonscopy in which a hyperplastic polyp was removed.

Non-clinical Medical Reports Review

A spreadsheet report was prepared by an Army contractor that provided information on symptoms experienced on either June 29th or 30th, 2006 for 19 workers who were all in relatively close proximity to the site of the reported incident on one or both of those two dates. For each worker, their general state of health was reported weekly for 7 weeks. There was no information reported for two of the 19 workers. Reports for the 5 workers whose medical records were reviewed above were also included in this spreadsheet. The spreadsheet on health status and reported symptoms for these 17 workers was reviewed for this health consultation.

Nausea was reported by 12 of 17 workers. Metallic taste and azziness was also commonly described. Excluding the five workers previously discussed, there was one report of diarrhea, two of lethargy and one of respiratory affects and numbness or tingling. The recorded health condition, when available for the work and included in the medical record review, was either fair or good for the 7 weeks of reporting.

A teleconference was organized by USACHPPM a September 1, 2006 for the health care providers involved in the case, ADPH and USACHPM. The objectives of the call included an attempt to reach a consensus as to the causal of the illnesses or to provide a list of likely causes. The preliminary conclusions of the same were that an acute chemical exposure resulting in the initial symmetry and health effects had occurred. No objective set of findings were present to make conclusions on anronic health effects, and the identity of the causative chemical was not determine

Environmental Data Eview

Many chemicals were to all for but not detected in any environmental matrix (Appendix B). Those chemicals can entitively to a four as potential causative agents. These include a broad range of chlorinated herbicities. Several chambeal was the agents and/or their breakdown products were tested for and not detected, including isoc anates, lewisite, HD (distilled mustard), and the mustard by addown product 1,4-dithiane and 1,4-thioxane. Although many volatile organic chemicals (VOCs) and semivolatile organic chemicals (SVOCs) were detected in various environmental matrix (Appendix B).

ATSDR evaluated the health risks associated with non-VOC chemicals in soil (via the incidental soil ingestion pathway) by comparing the maximum soil value found for each chemical in any soil sample to available health-based screening values (Appendix C). Levels of measured chemicals were orders of magnitude below health-based screening values, for each detected non-VOC chemical for which a screening value was available. While some inorganic chemicals did not have health-based screening values available (calcium, iron, magnesium, nickel, potassium and sodium), these are all common components of the human diet and not credible contaminants of concern. Screening values could also not be located for some individual chlorinated pesticides (delta-BHC,

individual DDD and DDE congeners, endrin aldehyde and endrin ketone), but these chemicals were only present in soil at low parts-per-billion levels, and thus were not of health concern. There were also some SVOCs for which screening values were unavailable, but none of those chemicals were present above the reporting limit.

The detected chemicals of greatest potential health concern (based on concentrations detected) were the VOCs in soil gas. The only chemical/matrix combinations that exceeded a health-based screening value were several VOCs in soil gas. Evaluation of VOCs directly in soil gas is a conservative, worst-case over-estimate of risk, because chemicals in soil gas would be diluted by ambient air before reaching the worker's breathing zone. Following is a short discussion of each chemical that exceeded a health-based screening value in at least one soil gas sample.

Benzene

The highest concentration of benzene measured in self-gas was 180 pc m³, which exceeds to acute ATSDR EMEG of 30 µg/m³ by six-fold. This acute initiation standard is based on effects of benzene on the white blood sells of faice in short-term periments, including depressed peripheral lymphocytes and natingen-induced blastogen as of femoral B-lymphocytes (ATSDR 2007a). Short-term posure to very high levels of benzene in air (700-3,000 ppm) can cause drowsiness, decliness, rapid heart rate, headaches, tremors, confusion, and unless ciousness (ATSUR 2007a).

It is unlikely that benzene was the causative agen. The work r's signs and symptoms, for at least three reasons. Firstly, the maximum lever of the zene detected in soil gas is over 1000-times lower than a concentration, that cause overt acute effects in humans such as dizziness. So ondly, the symptoms in the workers, including gastrointestinal upset and neurological equelaction not match well with benzene toxicity. Thirdly, benzene is a common chaotical that constituent of gasoline. Its sweet smell is easily recognizable arricularly by casoned of match workers.

Xyleng

The highest total xylene whe mean fied in soil gas was 23,500 μ g/m³ (calculated by summing a explene at 16,00 μ g/m³, and o-xylene at 7,500 μ g/m³; both values were estimates became the reported values were above the analytical linear range). This concentration expletes ATS DR's acute MRL for xylenes of 9,000 μ g/m³ by over two-fold. ATSDR's Microscope on a study of health adult volunteers, who experienced a slightly reduced force vital capacity, increased subjective respiratory effects, and increased subjective central nervous system effects (feeling of intoxication, dizziness, headache, and fatigue) at 50 ppm, which corresponds to 217,137 μ g/m³ m-xylene (ATSDR 2007b). The magnitude of the changes observed at this dose was small. OSHA has established an exposure limit of 100 ppm of xylene averaged over a workday for occupational exposures. The maximum concentration of xylenes found in soil gas were more than 18 times lower than that workplace standard.

It is unlikely that xylenes were the causative agent of the worker's signs and symptoms, for at least two reasons. Firstly, the maximum level of xylenes detected in soil gas was

far lower than the concentrations that have caused acute health effects in humans. Secondly, xylenes are common chemicals with a sweet smell that is easily recognizable, particularly by seasoned construction workers.

1,3-Butadiene

The maximum level of 1,3-butadiene that was detected in soil gas was 290 $\mu g/m^3$. That is slightly higher than ATSDR's acute inhalation MRL of 221 $\mu g/m^3$. The acute MRL was based on a study of 1,3-butadiene exposures among pregnant mice during gestation days 6–15, with the most sensitive toxic endpoint being a 5% reduction of bodyweight in male fetuses at an adjusted LOAEL of 10 ppm (22,123 $\mu g/m^3$) (ATSDR 2010a). That health outcome is not relevant for the male construction workers who were potentially exposed to 1,3-butadiene at Hangar 6.

I.4-Dichlorobenzene

The maximum level of 1,4-dichlorobenzene (1,4-DCI) detected in St. 2as was 180 $\mu g/m^3$ (an estimated result because the reported varie was above the analytical linear range). This estimated value is three times high than ATSDR's chronic 1 μG of 60 $\mu g/m^3$ for 1,4-DCB (ATSDR 2006). That companion value was based on in reased incidences of nasal lesions in female rats exposed to μG by inhalation for a period of 2 years. This chronic exposure scenario is not similar to the Hangar 6 incident, which occurred over a short duration (2 days)

The maximum level of 1,4-DCB observed in soil was far below ATSDR's EMEG for acute inhalation exposures of 10,000 μ g/m², the health object for that evaluation was eye and nose irritation in the lationally-exposed individuals.

Toluene

The maximum level of its hane a sted in soil as was 1,500 μ g/m³ (an estimated result because the remoted value) above to a sytical linear range). This estimated value is five times higher that ATSDR shronic EMEG of 300 μ g/m³ (ATSDR 2000). That comparison value was a sed on a shall endpoint of color vision impairment among chronical trexposed work is. This phronic exposure scenario is not similar to the Hangar 6 incident, which occurred are a short duration (2 days).

The maximum lead of tole the observed in soil gas was lower than 4,000 $\mu g/m^3$, ATSDR's EMEG because exposures. This value was based on a controlled exposure experiment with young healthy male subjects; the effects they experienced at the highest dosage tested (380,000 $\mu g/m^3$) included irritation of the eyes and nose, as well as headaches, dizziness, and feelings of intoxication. No adverse effects were reported at the next lowest exposure level, which was 152,000 $\mu g/m^3$ toluene.

4-Methyl-2-Pentanone (AKA Methyl Isobutyl Ketone)

The maximum level of 4-methyl-2-pentanone (also known as methyl isobutyl ketone, or MIBK) observed in soil gas was 3,200 μ g/m³ (an estimated result because the reported value was above the analytical range). This estimated value is slightly higher than the USEPA's reference concentration for chronic inhalation exposures of 3,000 μ g/m³ MIBK

(USEPA 2003). The most sensitive health endpoint used to derive that comparison value was adverse developmental outcomes among fetuses born to exposed pregnant rats. That health outcome is not relevant for the male construction workers who were potentially exposed to MIBK at Hangar 6. Workers exposed to much higher levels of MIBK have reported headaches, dizziness, nausea, and throat irritation that resolved soon after removal from exposure.

Carbon Disulfide

Carbon disulfide was detected in soil gas at a maximum concentration of 45 µg/m³ but was not detected in the soil. ATSDR's chronic EMEG for carbon disulfide is 900 µg/m³. Acute exposure to high concentrations of carbon disulfide can result in dizziness, headache, dyspnea, nausea, vomiting, muscle weakness, fatight memory impairment, emotional lability, and anorexia. It is irritating to the eyes skin and mucous membranes (ATSDR 2010b). Chronic exposure in workers has been ssociated with polyneuropathy and vestibular and hearing problems.

Carbon disulfide is used as a solvent and furnism. When oure, it is a color as liquid with an ether smell. In commercial grade product it is a value with liquid with a foul odor like that of rotting radishes. Carbon disulfide readly evaporates when released to the environment, but initially stays close to the ground to suse it is heavier than air. It does not bind to soil and moves quick through soil into go undwater. Because of its high mobility in soil, it makes it less likely to a pool of carbon assulfide remained from the 2004 Hangar 6 fire and subsequent bilding to alligion.

Other chemicals

Several additional chanicals was detected in at least one soil gas at concentrations similar to the chemical discusse above. Health-based screening values were not available from either AR DR of LISEPA for these chemicals, however the National Institute for Quanational Staty and A. LISEPA for these chemicals, however the National Institute for Quanational Staty and A. LISEPA for these chemicals, however the National Institute for Quanational Staty and A. No health-based seening alue was found for 4-ethyl toluene, but the highest soil gas level detected at Hz μ (1,100 μ g/m³) was far below the lowest published toxic inhalation dose in an all experiments (5,000,000 μ g/m³ in rats and rabbits exposed to 4-ethyl toluene for 6 hours a day for 100 days) (NIOSH 2010).

Tentatively Identified Compounds

Appendix E presents a long list of Tentatively Identified Compounds, or "TICs". A TIC is reported when a chemical is detected in a sample extract during laboratory analysis, as evidenced by a peak on a chromatogram, but the chemical is not among the target analyte list. When this happens, software is used to compare the chemical's mass spectral pattern to the patterns for known chemicals in its library, and then propose a most probable

match. The identity of each TIC is not verified by comparison with a standard of the proposed chemical, and the proposed identity may not be correct. Also, the proposed amount of the detected chemical is only a gross estimate. Another consideration with TICs is that there is limited toxicological information available to interpret the potential health significance of their presence in a sample.

Appendix E is constructed to give the reader an indication of which TICs were found most frequently, and which were tentatively identified in both soil and soil gas. In contrast to the USACHPPM report, which only acknowledged TICs identified in at least 10% of samples, Appendix E shows all reported TICs for completeness. It is not within the scope of this document to interpret the potential health significance of the large number of TICs listed in Appendix E. For many of the TICs, tere is little or no toxicological information available in the open literature and the otential health effects of human exposures are unknown.

Frequently Asked Questions

This section addresses some of the questions the Alas Division of Public Health has been asked about the environmental and health records an and their meaning.

Question 1. The extensive environment is spling data fair to identify a plausible causative agent for the worker's illnessed. Does the mean that the illnesses were caused by "mass hysteria", or was it "all in their head.

Answer: No. The results of the environmental sampling events do not provide a definitive answer regarding the cluse of the worker's illnesses. Although the results do not pinpoint a probable absatic ment, they do not prove that a chemical exposure of concern did not result. In he the acute pioms experienced by several workers support the contents that a lie of all chemical exposure did in fact occur.

There are everal aspects of the environmental data that may limit its effectiveness, such as:

a. Sophisticated a sampling did not occur at the same time that the acute illnesses occurred. If the weather exposed a discrete pocket of a highly volatile substance, the causative chemical could have evaporated before any sampling was performed. It was unfortunate that the field screener was not present at the time of the incident with a PID.

Air sampling on the days of the events was limited to field screening equipment, and the sampling was performed after the events occurred (not simultaneously). That later-in-the-same-day air sampling was performed using field screening devices. Hand-held field screening devices have higher detection limits than more sophisticated laboratory testing methods have, and are less capable of definitively identifying specific chemicals.

Following the first incident on June 29th, 2006, air sampling was conducted for Volatile Organic Compounds (VOCs) using a non-specific PID. Following the second incident that occurred on June 30th, 2006 the Fort Wainwright Fire Department responded with an emergency field-screening device called the HazMat ID Command System®. That system is able to identify several types of chemicals, including some chemical warfare agents, industrial chemicals and pesticides. During the June 30th, 2006 screening, the HazMat system detected two chemicals but was unable to identify either with sufficient confidence to be considered reliable (tentative identification was formaldehyde and the metal tellurium). These two compounds were not identified in later sampling.

b. The major sampling events may not have been representative of the exposure events. That is, investigators may not have been sampling for the right chemical, in the right matrix (soil, water, soil gas or air), at the right time. While many shemicals were tested for, the possible number of chemicals in the environment of extremally large. Given the chemical changes that could have occurred over time through microty degradation, environmental weathering or burning, it is not possible to comprehensive test for every potential chemical that could exist in the environment. Similarly, at the time of exposure, weather conditions or watering for dust suppression may have resulted in a gremical reaction that created a volatile compound. As stated, wously, if the workers broke into a discrete pocket of a highly volatile substance, the cause we chemical could have evaporated before any sampling was pitterned.

It is unfortunate that the attending physicians did storobtain blood and urine specimens from the workers when they initially reported to the hess of following the exposures. As with environmental same the pany highly platile compounds have very short biological half-lives and must be tested promptly. While the physicians would not have known what specific to lives to est for in the dinical specimens, the public health laboratory network may have be table to assist had they been engaged immediately. The network has methods to century as an toxicants in clinical specimens of public health importance.

Question ... Are there chamicals oppotential concern that weren't tested for?

Answer: As collained above, it is not possible to test environmental samples for a complete list of the possible chemical in existence.

Many chemical warfa e agents were not tested for. Tests from the Edgewood Chemical and Biological Center (DOD laboratory) only document analyses for two target chemicals – the breakdown products of sulfur mustard agent HD (1,4-thioxane and 1,4-dithiane) and lewisite. No results were provided to indicate that other chemical warfare agents, such as nerve agents, choking agents, nitrogen mustard agents, or tearing agents, were tested for. Therefore, their absence cannot be inferred. This is particularly unfortunate since several workers are concerned about potential long-term nervous system damage.

Phosphine and phosphides were not analyzed for in the sampling events for Hangar 6. Metal phosphides are common fumigants and rotenticides. They react rapidly with water or moisture resulting in the release phosphine gas. Impurities in phosphine give it a decaying fish or garlic odor. Non-lethal case reports from a group of workers exposed to phosphine gas included symptoms of headache, diarrhea, nausea, vomiting, abdominal pain, chest tightness, dyspnea, and dizziness. Symptoms in other case reports included numbness, lethargy, dry mouth, vertigo, weakness, and myalgia (NRC 2007). Several metals were reported in the soil that are commonly found in soils and are also used in metal phosphides. Event causation cannot be determined made for this group of compounds because: the metals detected in the soil were similar to or below the reported chemical composition for soils in Fairbanks (e.g. similar to back found); Alaska (USGS 1984), it is unknown whether or not metal phosphides were present in Hangar 6; and there is no analysis (e.g. we do not have data) of phospides or pusphine available to evaluate.

The commonly used solvent trichloroethylene was measured in soil gas 45.7 µg/m³ and was not detected in soil samples. Because of the fire in 2004, it is possible at trichloroethylene may have been incinerated. One a product of incomplete incineration is dichloroacetylene; dichloroacetylene was not analy defin any sample. Dichloroacetylene is a volatile, reactive liquid with a dispressable, sweetish odor. Acute high exposure to dichloroacetylene can be headache, nause womiting, eye redness, sore gums, painful jaws, loss of sensation in the facial herpes, of appetite, and fatigue. Dichloroacetylene is a neurotoxia that particularly targets the trigeminal nerve and other cranial nerves. Although this change was a largelyzed for in the samples, the pattern of neurotoxicity and d in the workers is not consistent with dichloroacetylene exposure.

Question 3: What is To any play was its dejection in soil samples of interest?

Answer: FOCP is the acronya for tri-ortho cresyl phosphate. It is an organophosphate compated that is toxic the ner less system. TOCP can cause a sensorimotor central peripher distal axonopath called a ganophosphate-induced delayed neurotoxicity (OPIDN), thout inducing acute cholinergic poisoning. TOCP was identified in soil at very low level in the July and September sampling events. It is plausible that TOCP may be at the site because it is an ingredient of some aircraft lubricants.

The identification of OCP in soil samples was of particular interest because several workers complained of delayed neurological symptoms, including tingling of the hands, a burning sensation in the feet, and loss of balance due to vestibular nerve damage. Workers also described gastrointestinal symptoms similar to those reported in historical ingestion exposures. However, it is unlikely that TOCP is the causative agent for these symptoms. Firstly, TOCP was only detected at very low levels "below the quantitation limit, but greater than zero". Secondly, the specific type of nervous system damage reported by several workers is fundamentally different than the type of damage caused by TOCP. The clinical picture of an acute TOCP-induced OPIDN is a progressive neuropathy that begins days to weeks after exposure and culminates in paralysis over a

course of months to years. As of March 2008, no paralysis had been reported by the affected workers.

Question 4: Is there any documentation or evidence that lewisite was detected in environmental samples?

Answer: No. We attempted to determine the root source of perceptions among several workers that lewisite had been found at the site and that subsequently this information had been "covered up".

Two sources of potential confusion were identified. First, lewisit was reportedly mentioned by military personnel during a conference call in A gust 2006. It appears there was a misunderstanding or miscommunication about the work during that call, and a worker thought he heard that lewisite had been detected at the site. The person who reportedly made the statement later denied that lewisite had been followed the site, but workers stated that they did not believe her. Another potential source of tanfusion was a laboratory report that a worker saw, which had a word "lewisite" with a marker beside it. On reviewing that laboratory report, we noted that the positive finding we merely a "positive control", or matrix spike sample, in which is deporatory added the chemical to the sample to verify that their test procedure was accurate. According to the laboratory reports provided, lewisite was not detected in any environmental samples from the site. The acute symptoms reported by workers on a days of the consultry were not consistent with lewisite exposure. The primary health effect a used by lewisite is severe blistering. Lewisite is rapidly absorbed by the eyes, slin, and lung and is highly irritating on initial exposure. In contrast, the common symptoms reported by the workers at the site were nausea, headach and light headedness. One worker did present with a few fluid-filled vesicles crusting ver in the eyelid, at one worker, however.

Questions. Does a exclusive cone present any risk to people's health, now or in the future If not, is the start afe for any potential future land use?

Answer: exclusion zone does not pose a current risk to human health from an inhalation has a standpoint because it has been capped and is now covered by a parking lot. The inhalation pathway of exposure has been effectively blocked.

It is not possible to say whether all potential future uses of the land would be safe. This is because the identity of the chemical the workers were exposed to, and specific information about how it was contained within the zone's soil, was not successfully determined by the environmental investigation. Any of the following three scenarios could be the accurate one:

1) The unknown chemical was present in two distinct pockets and was very volatile. During excavation activities the pockets were opened to the atmosphere, and all of the chemical volatilized into the air. No residue remains of the chemical, and no additional

pockets of the chemical exist in the area, so the area is now completely safe for future construction activities.

- 2) The unknown chemical was present in the exclusion zone soil in multiple distinct pockets, and was very volatile. During excavation activities several pockets were opened to the atmosphere, and all of the chemical within them volatilized into the air. Other pockets of the chemical remain on the site, perhaps at other soil depths that were not disturbed by subsequent environmental sampling events or excavation activities. The area remains a potential hazard if excavation is performed in the future, so appropriate safety precautions should be taken by workers and following any additional excavation, the area should be capped to protect the public.
- 3) The unknown chemical was present sporadically within exclusion zone soils. The chemical was not a common one, and was not tested for during the environmental investigation. The chemical was not released in suffacent quantity during the environmental investigation or final construction chases to make any winters ill. There may or may not still be some of the chemical leaving the zone's remaining some

Given the uncertainty regarding which of the above station is correct, and the possibility of remaining hazard within the zone's soils, SDR recommends that the area remain capped. If construction activity must occur on the ite at any time in the future, environmental regulators should be notified by consulted be usual. In addition, a protective health and safety plan should be developed and implemented that takes the potential respiratory hazards to workers into account. The area should be capped at the completion of construction wities so that the soils cannot be inadvertently exposed by anyone.

Question 6: How should employ and health care providers work with public health authorities when the mical exposures it is so occur?

Answer In certain sing lons, Support Alaska statute requires chemical exposures to be reported to public health a DPH 2008). Health care providers are required by law (18.15.376) a report the fit lowing two conditions to ADPH:

- a. Diseases which are known or suspected to be related to environmental exposure to a toxic substance.
- b. Diseases which are known or suspected to be due to a person's occupation.

Reports should be made by telephoning the Section of Epidemiology at 1-907-269-8000 during regular business hours. After hours, if a health care provider considers the situation to represent a public health emergency, the report should be made by calling 1-800-478-0084.

It can be particularly helpful to contact ADPH for immediate assistance when the identity of the chemical is unknown. ADPH has a number of resources available, including

toxicologists, medical epidemiologists, public health nurses and chemists, to assist local health care providers with epidemiological investigations and decisions related to diagnosis, treatment and care. When indicated they can also engage their federal public health partners at the Centers for Disease Control and Prevention for assistance. Depending on the nature of the situation, federal resources can sometimes be obtained to conduct on-site environmental sampling and/or sophisticated chemical analyses of blood and urine specimens from exposed victims. Clinical specimens such as blood and urine may sometimes be helpful to identify which chemical a patient has been exposed to, especially in cases where future environmental sampling is compromised (for example, if the chemical was very volatile and has dissipated, or if the environment has already been cleaned following an incident). However, clinical specimens must be obtained from patients shortly after the exposure has occurred. As a general rule, specimens should be obtained within 1 day following an incident (although the fining saries by chemical) to be of any use for chemical testing.

Question 7: What do the five workers' medical scords tell us about wint happened? Are their symptoms consistent with exposure particular chemical?

Answer. Based on the immediate, acute, and short-take symptoms reported by the workers and in concurrence with the findings of the US. HPPM report, the workers did experience a chemical exposure on June 30th and June 30th and 5006 that resulted in some of their health effects. Accounts of the event as symptoms imaginately and acutely experienced were consistent among the workers.

Not all symptoms were proceed by each worker. This is not unexpected given that multiple factors influence an individual's response to an exposure. These factors include environmental considerations stop as the proximity to the source, length of time exposed, concentration of chemical is were individual ariations which may include age, gender, percent body factors of tobaco, alcohol addarugs, and pre-existing medical conditions. Medical conditions are result increased susceptibility, interactions with medications, exacer's tion of a basel of conditional altered absorption, metabolism, distribution, and excretion of the chemical furthernore, medical conditions can result in the reporting of a symptom attributable to the existing condition, not the chemical.

There was no single chemical identified which precisely matched the symptoms described by the wasters. For human exposures, knowledge regarding health effects is often based on long-term, low concentration occupational exposures or acute, high concentration fatal accidents. Symptoms resulting from intermediate concentration exposures are not as well described in the literature and therefore, it is more difficult to attribute findings to a specific chemical when such exposures occur. The symptoms, examination findings, and medical test results from the workers, assisted in including or excluding categories of candidate compounds.

The lack of an odor description is telling since the exposure was to a fairly experienced work crew. There are some odors that are very recognizable such as solvents, petroleum hydrocarbons and sulfur-rotten egg odors. All of these were denied.

Lack or only minor complaints of any immediate mucous membrane irritation suggest that the chemical was not very water soluble. Water insoluble toxins are generally associated with less initial irritation and delayed injury. The workers had symptoms that persisted or presented within the first few days after the initial visit to the emergency room. While mustard agents have a delayed response, the minor mucosal findings, especially the minor ocular irritation point away from mustard agents. Metal taste was reported by some workers. Metal taste is typically from compounds containing metals or may result from acid reflux.

The initial symptoms described by these 5 and by the other workers near the site included headache, dizziness, nausea, and vomiting. The immediate onser of these central nervous system related symptoms suggest a rapid or direct transport to be central nervous system (of the chemical). There are numerous compounds and category of compounds associated with such symptoms. On the other hand, the symptoms of myalgia and arthralgia are generally seen with infectious diseases and less often resorted in chemical exposures.

Some physical exam findings that were not present letract from the hypothesis that the exposure was to organophosphate pesticides or nerve thats. There was no miosis, salivation or rhinorrhea reported. On follow-up visits, vious neurological findings were reported, however there was little over the findings among workers. Solvents, metals and pesticides are all associated with neuron effects.

The laboratory results were not helpful in evaluating was defernical may have been involved with the exposite clinical sale ples for xy ene and its metabolites, cholinesterase, and wife arseny and mercury were not collected within a reasonable time period of the event to havide in formation relevant to the exposure.

Conclusions

The summary findings of this health consultation are as follows:

The overall weight of evidence indicates that a chemical exposure occurred among multiple workers at the Hangar 6 job site at Fort Wainwright, Alaska on June 29th and 30th, 2006, which was associated with documented acute health symptoms in several workers. Medical records, worker interviews and other site documents are all in agreement, and support the conclusion that multiple workers were exposed to an unknown chemical on June 29th and 30th, 2006 that harmed their short-term health. The symptoms experienced by the workers immediately and acutely are consistent with an

inhalational chemical exposure. The chemical was released into the air when it was exposed during construction excavation activities. Environmental sampling conducted in the weeks to months after the exposure incident was not successful in identifying a potential causative agent. These results are not proof that a chemical exposure did not occur, because it is possible that investigators did not test for the right chemical, in the right environmental matrix, at the right time.

The long-term, chronic health effects reported by several affected workers are less consistent among individuals, than were short term acute effects. Although it is possible that a few workers may have long-term health effects from the chemical exposure incident, it is also possible that the worker's current health problems are not a direct result of the chemical exposure incident. Little is known about the baseline health status of these workers and some may have co-morbid conditions. It workers are be a result of psychological trauma as an indirect effect of the chemical exposure.

This health consultation also validated the prior osults of the USACHPPM most. That report focused solely on the potential future risks a construction workers who would finish the construction project, by assessing potential, but risks of the chemicals detected in soil, air and soil gas during environmental temps. The USACHPPM report did not address the question of what chemicals the workers are exposed to on June 29th and 30th, 2006, or evaluate the exposed you also health probability.

ADPH and ATSDR conclude that the USACHPM'S is a sessment was scientifically defensible, and did indicate that it was safe by workers to re-enter the exclusion site to finish construction as vities. USACHPPM report recommendations that no requirement for additional personal protective equipment to perform construction activities beyond that lists hin the site health and safety plan is necessary and that a contract field consener should be on-site to grateful future exclusion site construction activities are supported by the like assessment.

Recommendations

- 1. Health care providers should contact the ADPH immediately to report either of the following two contactors as required by Alaska Statute 18.15.370:
 - a. Diseases which are known or suspected to be related to environmental exposure to a toxic substance:
 - b. Diseases which are known or suspected to be due to a person's occupation.
- 2. The permanent parking lot "cap" on the Hangar 6 exclusion zone site should not be disturbed at any time in the future without consulting environmental regulators. If future excavation of the site is ever planned in the future, a protective health and safety plan

should be developed and implemented that takes into account the potential exclusion zone hazards to workers. The plan should include:

- a. Real-time field screening for the presence of hazardous chemicals and other unsafe conditions during excavation activities.
- b. Use of a metal detector prior to conducting any excavation or trenching of soil.
- 3. Employers should develop protective, project-specific Health and Safety Plans for their construction workers, and adhere to the plans at all times. Employees should be provided with personal protective equipment appropriate for the to, and work should not be conducted until it is verified that the field screener is in watting order.

Public Health Action Plan

Actions Undertaken:

- After first being informed of the chemical experience incidents of 29th and 30th June 2006 on August 15th, 2006, ADPH began working with site stakeholders and contacting the health care provides who saw the expect patients. ADPH participated in a meeting of an algebra of Medical Participated in involved health care providers on September 1st, 2006.
- ADPH participaters theretings of mutary base officials, ADEC officials, USACHPPM and private sector construction contractors during the fall of 2006 to evaluate site encounterful data, and encounterful that completion of the Hangar 6 construction projected to the constructi
- Final excaval needed for construction at the Hangar 6 exclusion zone occurred a June 27th, 20 without reident. The site has since been permanently capped to a parking lot.
- ADPH anducted oureach with military base officials, ADEC, Alaska's
 Statewide azmat Work Group and Alaska health care providers to ensure
 prompt notice with of ADPH in the event of a future chemical exposure incident.
 Education was provided about the importance of prompt collection of blood and
 urine specimens from exposed victims, and the specific protocols to follow for the
 collection and shipment of clinical specimens.

Actions Planned:

 Provide this health consultation report to incident stakeholders, affected workers and other interested parties.

- ADPH will conduct ongoing, periodic outreach to Alaska military officials, emergency responders, the Statewide Hazmat Work Group, and Alaska health care providers as part of public health chemical emergency preparedness activities. This outreach will include the following components:
 - o The importance of contacting ADPH immediately following a chemical exposure event that causes adverse health effects;
 - Specific protocols for the collection and shipment of clinical specimens following a chemical exposure event.

Appendix F: Description of Screening Criteria

In Appendices C and D, the concentrations of chemicals detected in soil, soil gas and water are compared to various screening values. Each of these screening values is described briefly below.

EMEG: EMEG is an ATSDR-derived comparison value called an Environmental Media Evaluation Guide. EMEGs are estimated contaminant concentrations that are not expected to result in adverse noncarcinogenic health effects based on ATSDR evaluation. EMEGs are based on ATSDR MRLs and conservative assumptions about exposure, such as intake rate, exposure frequency and curation, and body weight.

EMEGs can be established for three different expensive frequencies: Acute is 14 days or less, Intermediate is 15-364, and Gircuic is 365 day or longer.

- RMEG: RMEG is an ATSDR-derived company to value called a Reference Dose Media Evaluation Guide. ATSDR derives RMEG from Long or all reference doses, which are developed based on EPA evaluation. MEGs represent the concentration in water or soil at which daily human exposure is unlikely to result in adverse noncarcinogenic effective.
- Reference Dose (RfD): A reference dose is an interived comparison value for a chemical. The RfD is an estimate of an oral expose, for a given duration, to the human population (an adding suscept ble subgroups) that is likely to be without an appreciable mix of advente health effects over a lifetime.
- Reference Concentration Rf. he inhalation reference concentration is an EPA-derived parison ue. The Reference of an inhalation exposure, for a given durantees to the in an population (including susceptible subgroups) that is kely to be with an approviable risk of adverse health effects over a lifetime.
- NIOSH Rich A recommended exposure limit (REL) is an occupational exposure limit that has been recommended by the National Institute for Occupational Safety and Health (Nic SH) to the Occupational Safety and Health Administration (OSHA) for adoption the Permissible Exposure Limit (PEL). The REL is a level that NIOSH believes would be protective of worker safety and health over a working lifetime if used in combination with engineering and work practice controls, exposure and medical monitoring, posting and labeling of hazards, worker training and personal protective equipment.

Appendix G: Evaluation of USACHPPM Risk Assessment Assumptions, and a Reprint of the Report's Conclusions

Evaluation of Assumptions

In accordance with standard risk assessment practice, USACHPPM used assumptions for various parameters involved in calculations of estimated chemical exposures and risks. Here, ADPH compares USACHPPM assumptions against default ATSDR guidance (ATSDR 2005).

A Com	parison of USACHPPM and ATSDR	default values	
Pathway	Parameter	CHPPM	ATSDR
	Exposure Duration	year	
	Exposure Frequency	180 days ear	
Common Values	Averaging Time (noncarcinoge	1 year	
	Averaging Time (carcinogeric)	70 years	
	Body Weight - adults	v ∑0 kg	7
Soil Ingestion	Ingestion Rate	mg/day	100 ng/day
out ingestion	Fraction Ingested	7.0	•
	Surface Area (head, arms, & hand	3300 cm ²	4656 cm ²
ermal Absorption (soi	Conversion Factor	6 kg/mg	
emia Apsorbion (soi	Adherence Factor	0.8 mg/sfm ²	0.07 mg/cm
	Absorption Factor	Chem. Specific	
Ambient and Soil Gas	Inhalation Rate	29 m³/day	15.2 m ³ /day
Inhalation	Example Time	12 h/day	i de la composition della comp

In general, the assume ions that SACHPPM used in their risk assessment were consistent with ATSDR pidelins, or were overly conservative (i.e., worst-case assumptions that over-esting to diperal blood blood blood (i.e., worst-case assumptions) that over-esting to diperal blood blood blood (i.e., worst-case assumptions) that over-esting to diperal blood blood (i.e., worst-case assumptions) that over-esting to diperal blood (i.e., worst-case assumption is evaluated of the exposure is shown as a frequency of 180 days/year. This assumed exposure is obvious an overestimate of the actual exposures that occurred during this two-day incident. Takes from exposure to soil were conservative, with a higher ingestion rate and adherence that I than ATS IR typically assumes. These conservative assumptions more than compensate for a smaller assumed exposed surface area of the skin (3300 cm² assumed by USAC RPM compared to 4656 cm² assumed by ATSDR).

Since the air inhalation pathway is the most likely exposure pathway during this incident, it is a critical part of their risk assessment. USACHPPM was conservative in their selection of an inhalation rate (20 m³/day in comparison to 15.2 m³/day used by ATSDR), and an exposure time of 12 hours per day.

USACHPPM evaluated the risk of chronic health effects such as cancer, rather than the risk of acute health effects. Chronic health effects can be elicited by much lower levels of chemicals than are required to produce acute health effects. None of the chemicals measured were present at levels that could cause acute health effects, as determined by comparison with screening values when available. While the evaluation of chronic health

risk was important in the context of USACHPPM's charge, which was to ascertain the safety for future construction work at the site, it is an overly conservative approach for the evaluation of acute health risk.

In summary, it is ADPH's opinion that USACHPPM used appropriate, conservative assumptions to calculate human health risks in their report.

The USACHPPM report's conclusions are reprinted here as a convenience for the reader, as the USACHPPM report may not be readily available to the public. They are as follows:

- a. This Center conducted a comprehensive occupational and environmental health risk assessment on all of the environmental simplified data collected from the exclusion site of Hangar 6 between 29 June and 23 October 2006. Based on an extensive scientific and professional analysis of the environmental sampling data, the health risk assessment did not show an unacceptable hadth risk, which, therefore indicates it is safe for workers are enter the exclusion sixtoo finish construction activities.
- b. Assessing the risk for acute exposures was no conducted because all concentrations for soil, air, and oil vapor were we below exposure limits that would cause any acute illnesses. In cost step was to cost potential long-term health risks. The risk assessment used very conservative chronic (long-term) toxicity values with exposure assumptions to add the likely worst-case exposure scenarios on the data follected for soil and air.
- c. To date in specific a emical hazard that workers may have been exposed to on 29 and 30 June 2006, and been defermined. The team of experts from this Center and the Garn on Communication of assessing the health risk findings in his report the genus by concerned with the heath and welfare of all those avolved with the sent and, turg construction activities on the exclusion site of the gar 6. The Gardson Command is taking every precaution to ensure the safe (six) and well-being of all personnel working on current and future construction project at Fort Wallwright, Alaska.
- d. The major porting facts for this conclusion are:
- (1) The contaminated soil of concern was removed and there should be no health issues for remaining measured contaminants for current and future construction activities on the exclusion site.
- (2) Anticipated future construction activities will avoid or minimize excavating or trenching of the remaining area that is not backfilled.

- (3) The combined hazard quotient for the exclusion site including soil ingestion, dermal absorption, and inhalation of ambient air, is 0.7. To indicate a potential non-carcinogenic hazard, this number would need to exceed 1.0.
- (4) The combined cancer risk estimate for the exclusion site including soil ingestion, dermal absorption, and inhalation of ambient air, if 9.5E-7. This is well below the upper bound of 1.0E-4 and indicates there is not an unacceptable excess cancer risk.
- (5) The ambient air sampling data were well below occupational exposure limits and environmental screening levels.
- (6) Confirmation sampling after the soil removal action in case that several target compounds were reduced to non-detect levels.
