

Explanation of "3 Tables Comparing 500 mrem/yr DRL Concentrations to MCL or 1×10^{-4} Concentrations"

There are 3 Lotus 123 Tables provided. They are sorted by:

1. Radionuclide, in the order provided in the draft PAGs chapter
2. Risk, in order of the DRL posing the highest multiple of a 1×10^{-4} cancer incidence risk
3. MCLs, in order of the DRL posing the greatest multiple of the MCL

Rationale for Tables 2 and 3:

The CERCLA document most analogous to this PAG would be the "Final Guidance on Numeric Removal Action Levels for Contaminated Drinking Water Sites" OSWER 9360.1-02, October 25, 1993, which discusses when short-term risks from contaminated drinking water wells are high enough to warrant providing alternative (replacement) drinking water supplies. For class A carcinogens that do not have DWELs or longer-term HA's, like radionuclides, this guidance says to provide drinking water if the concentrations are above 1×10^{-4} lifetime risk (using OW methodology of 70 year exposure), or the MCL, if the MCL is greater than 1×10^{-4} lifetime risk.

Following are explanations of the information in the 3 tables.

Radionuclide column:

- Lists of radionuclides taken from Table 4.2 in draft Chapter 4 on drinking water PAGs.
- Radionuclides that are bolded and their rows are shaded were considered radionuclides of most concern for RDDs, INDs, or nuclear accidents in writeups from ORIA and Army Corps of Engineers.
- Tables that were put in the same row in Table 4.2 (e.g., Ru/Rh-106) have been broken out to facilitate comparisons between DRLs and 1×10^{-4} risk levels.

DRLs with Rad Decay column:

- Taken from Table 4.2. These were the most stringent DRLs listed and were used for comparison purposes since the other DRLs used assumptions that would not factor into CERCLA decisions about when to provide drinking water (e.g., assuming levels will decay or dilute over the year so use a level averaged over the year).

1x10⁻⁴ using OW Methods column:

For those radionuclides that do have a value listed in the column "OW risk associated with MCL", these values are based on the rounded off values in the "OW risk..." column then a hand calculation on the value in the "MCLs" column to approximate the concentration that corresponds to a 1×10^{-4} cancer incidence risk using OW methodology. Note, OW staff did not create 1×10^{-4} concentrations for these radionuclides.

For those radionuclides that do not have a value listed in the column "OW risk associated with MCL", these values are from OW.

MCLs Column:

MCLs from OW implementation guide.

Uranium MCLs are in terms of mass (micrograms per liter), not activity (picoCuries per liter). The 30 micrograms per liter MCL for the uranium element was converted to an activity for each isotope. The UMTRCA groundwater standard of 30 pCi/l for U-234 and U-238 combined was listed here for U-234 since it is a potential ARAR at CERCLA sites.

OW Risk Associated with MCL

Provided in NODA for MCLs and/or regulatory support document. Note that some MCLs that are in OW implementation guide did not appear in the support documents, which is why SF rather than OW risk is provided.

1x10⁻⁴ using SF & 70 yrs

Risk estimate developed using CERCLA rad PRG calculator, by changing "Tap water" exposure scenario defaults as follows: time of exposure from 30 years to 70 years; target risk from 1×10^{-6} to 1×10^{-4} .

Comparison of DRL to OW/SF 10-4:

Shows by a factor of #, how much DRL is greater than 1×10^{-4} risk level concentration.

What this means

- if value is 70, then 1 year of drinking 2 liters of water at DRL value will equal amount of exposure of drinking water with a lifetime cancer incidence risk of 1×10^{-4} for a lifetime (70 years)
- if value is 840, then 1 month of drinking 2 liters of water at DRL value will equal amount of exposure of drinking water with a lifetime cancer incidence risk of 1×10^{-4} for a lifetime (70 years)
- if value is 25,550, then 1 day of drinking 2 liters of water at DRL value will equal amount of exposure of drinking water with a lifetime cancer incidence risk of 1×10^{-4} for a lifetime (70 years)
- if value is 127,750, then drinking 1 glass of water (12 ounces) at DRL value will equal amount of exposure of drinking water with a lifetime cancer incidence risk of 1×10^{-4} for a lifetime (70 years)

Comparison of DRL to MCL

Shows by a factor of #, how much DRL is greater than MCL concentration.

What this means

- if value is 70, then 1 year of drinking 2 liters of water at DRL value will equal amount of exposure of drinking water at the MCL level for a lifetime (70 years)
- if value is 840, then 1 month of drinking 2 liters of water at DRL value will equal amount of exposure of drinking water at the MCL level for a lifetime (70 years)
- if value is 25,550, then 1 day of drinking 2 liters of water at DRL value will equal amount of exposure of drinking water at the MCL level for a lifetime (70 years)
- if value is 127,750, then drinking 1 glass of water (12 ounces) at DRL value will equal amount of exposure of drinking water at the MCL level for a lifetime (70 years).
- For example, drinking a very small glass of water of approximately 4ounces with Bi-210 at the DRL concentration would result in an exposure that corresponds to drinking liters of water per day for 70 years at the MCL level.
